Hydrocarbon Injury Assessment
Kodiak and Alaska Peninsula Herring

Fish/Shellfish Study Number 12
Annual Report

Study History: This project effort was initiated as part of the State of Alaska and U.S. Government Natural Resource Damage Assessment (NRDA) studies following the *Exxon Valdez* oil spill. Results from this study were planned to be merged with results from NRDA Coastal Habitat Injury Assessment Studies (Coastal Habitat Study #1) and Air and Water Resources Injury Assessment Studies (Air/Water Studies #1-4) to identify potential injury or impact. In addition, results from studies of oil spill damage assessment impacts on herring spawning and recruitment in Prince William Sound (Fish/Shellfish Study #11) were expected to be merged with results from this study to estimate impacts on these stocks. This project was terminated after one year, however, and no further analyses have been completed.

Abstract: Pacific herring spawning aggregations were monitored by aerial surveys during 1989. The estimated spawning biomass in the Kodiak area was approximately 9,550 tons; however, the variability of this estimate is unknown and probably large. The historical record of pre-spawning and spawning aggregations was mapped and the records of herring length at age data from spawning areas from 1981 to 1990 have been summarized.

Key Words: Age, Alaska Peninsula, *Clupea pallasi*, *Exxon Valdez* oil spill, Kodiak Island, Pacific herring, size, spawning stocks.

Project Data: Archival location of data is unknown. All available information is included in this report.

EXECUTIVE SUMMARY

The occurrence and biomass of Pacific herring (*Clupea pallasi*) spawning stocks around Kodiak Island and the Alaska Peninsula in 1989 were documented by aerial surveys. The surveys were less than thorough because they began after spawning had started, and because of hazardous flying conditions and limited availability of charter aircraft.

Biomass estimates used by the Kodiak Area Management staff for setting "Guideline Harvest Levels" are the best estimates of the size of the Kodiak and Alaska Peninsula herring populations. The estimated spawning biomass in 1989 was approximately 9,550 tons. Maps of historical population aggregation areas and spawning areas were compiled to identify areas of potential oil spill impact. No direct herring mortality was observed in 1989, and an influx of juvenile herring (ages 1 and 2) was noted in many bays of the Kodiak area. Comprehensive damage assessment studies of oil impacts on herring fecundity, on egg deposition, and on egg and larvae survival and development were conducted in Prince William Sound, and the results from those studies were planned to be used to extrapolate probable damage on Kodiak/Alaska Peninsula stocks. Historical data on herring length at age, from age-weight-length-sex (AWL) samples taken during herring sac roe fisheries, 1981-1990, are being compiled and analyzed to test for year, area, and possible oil spill effects on herring growth.

INTRODUCTION

This project effort was initiated as part of the State of Alaska and U.S. Government Natural Resource Damage Assessment (NRDA) studies following the *Exxon Valdez* oil spill. Results from this study were planned to be merged with results from NRDA studies to identify potential injury or impact to Pacific herring stocks in the vicinity of Kodiak Island.

OBJECTIVES

No significant departures have been made from the objectives of this study, as outlined in the Detailed Study Plan. They were:

1. Document the occurrence of Pacific herring stocks and spawn in oiled and non-oiled areas of the Kodiak Archipelago and the Alaska Peninsula.
2. Estimate the injury to herring eggs and larvae by directly supplying results from Prince William Sound injury assessment studies.
3. Test the hypothesis that incremental growth by age is independent of oil impacts.
4. Identify potential alternative methods and strategies for restoration of fishery stocks, and/or habitat where injury is identified.

METHODS

With the inception of State/Federal Natural Resource Damage Assessment Plans, an Alaska Department of Fish and Game (ADF&G) fishery biologist was assigned to conduct fixed wing aerial surveys. The survey area comprised all of the Kodiak and Alaska Peninsula Pacific herring management areas (Figure 1). Special emphasis was placed on those locations where herring spawn had been reported or stocks were reaching sexual maturity, as indicated by ADF&G field personnel, commercial fishermen or spotters. Survey data was collected in field "Rite-in-the-Rain" notebooks, or on aerial survey forms. The location, number, relative size (small, medium, large), and an estimate of total biomass observed was noted for all schools of herring and forage fish. Location, duration, and size of spawn were recorded. Similar information was collected by ADF&G herring field crews. Additionally, observations from fishermen, spotters, or oil assessment crews were evaluated and included where possible.

Coastal habitat injury assessment studies (Highsmith, et al. 1993), in conjunction with air/water resources injury assessment studies (Braddock, et al. 1989; Feder 1995; Short and Harris 1996; Short and Rounds 1995), were intended to determine the extent of potential injury, or degree of impact, by habitat type and level of oiling (unoiled, light or moderate/heavily oiled). Impact of oil to all areas was evaluated using the same criteria developed for observational studies in Prince William Sound. Studies in Prince William Sound seek to determine the effect of the oil impacts on adult herring growth and fecundity, egg deposition, and egg and larvae survival and development through field and laboratory studies. Quantifiable damage assessment from the Prince William Sound studies was to be directly applied to the spawning stocks in similarly impacted areas of the Kodiak/Alaska Peninsula area.

The ADF&G has collected age-weight-length (AWL) and sex data from samples of Kodiak/Alaska Peninsula stocks during the sac-roe fishery since 1979 (Appendix A). Between 4,000-9,000 fish were sampled each year. Detailed methodology for collecting AWL samples is described in Appendix B. Length-at-age data are to be summarized, and a "pre-spill database" will be developed as a basis to compare future growth rates.

RESULTS AND DISCUSSION

Fixed wing, aerial survey flights began on May 26, 1989. This was after the start of herring spawning, but it was the earliest that funding would allow. Surveys were continued through July 11, 1989. Flight time was severely limited during that period because of the lack of availability of charter aircraft, which were diverted by the workload imposed by oil spill monitoring and cleanup crews and periods of poor weather. During this period, 16 surveys, with a total of 48.9 hours, were flown. Surveys were limited to the Kodiak Island Archipelago. Additional data were collected by eight ADF&G herring fishery monitoring crews, using inflatable rafts, aluminum skiffs, and a 40' research vessel, and ADF&G and Alaska Department of Environmental Conservation (ADEC) oil spill monitoring crews, using chartered vessels and helicopters.

Notably, no direct mortality of herring was observed by ADF&G or ADEC personnel. In addition, schools of juvenile herring (age 1 and 2) were documented by aerial surveyors and commercial fishermen in many bays of Kodiak Island. The 1989 Kodiak Area spawning biomass index, developed by the Commercial Fisheries Division management staff, was approximately 9,550 tons (Prokopowich 1989). These estimates should be qualified, however, because ADF&G's annual observations represent an unknown and undoubtedly highly variable proportion of the actual biomass. It has been estimated that as little as one quarter to one half of the actual biomass is observed for Kodiak area stocks (L. Malloy, ADF&G, Kodiak, pers. commun.). This is a result of: the relatively low biomass of these stocks; the numerous small schools associated with each stock; the long duration of time over which the entire spawning biomass for each stock disperses its spawning effort; and the relatively small amount of aerial survey effort which can be expended over the spawning period that extends from early April through early August. Results from the 1990 aerial surveys also documented large quantities of "pre-recruit" herring (ages 1, 2 and 3) in many of the bays in the Kodiak area.

Maps have been prepared to show areas where pre-spawning herring have historically aggregated and where herring have consistently spawned, based on data gathered by ADF&G and from observations by commercial fishermen and spotters during the sac roe fisheries of the past ten years (Figures 2-18). These, compared with documentation of observations of oiled beaches in the vicinity of Kodiak Island and the Alaska Peninsula, suggest that there may have been little overlap (ADEC 1990; Endres 1992; Ginalias 1991).

Comprehensive damage assessment studies of oil impacts on herring fecundity, on egg deposition, and on egg and larvae survival and development were scheduled to be conducted in Prince William Sound. Injuries described by results from those studies will be used to extrapolate impacts on Kodiak/Alaska Peninsula stocks. Please refer to the preliminary status report for Fish/Shellfish Study #11 (Brown and Baker 1994), and to the Kodiak/Alaska Peninsula Atlas and Regional Maps of Spring NOAA 1991). This study, however, was terminated before that extrapolation could be made.

Analysis of data on herring length-at-age is continuing. Of the AWL data collected from 1981 through 1989, there are sufficient commercial purse seine samples from 40 management units (36 on Kodiak Island and 4 on Alaska Peninsula) for analysis (Appendix A). The statistical significance of area effects on growth and between-year variability within areas was to be tested, but this project was truncated before that could be accomplished.

During the 1990 commercial herring fishing season, 7,671 herring were collected and sampled from 38 of the 51 statistical areas. AWL data on herring taken during the 1990 season was summarized and available for comparative analysis by October 1990. General linear model extension of analysis of variance models were not used to test for year, area, and oil spill effects on herring growth because there were no observations of direct oiling, and this project was terminated after one year.

CONCLUSIONS

- 1) Records and reports from up to ten years of observations of the distribution of spawning aggregations of Pacific herring in the Kodiak Archipelago and the Alaska Peninsula were recorded on charts. These, compared with a map of oiled and unoiled areas, suggest little overlap.
- 2) The estimated spawning biomass of Pacific herring in the Kodiak area was approximately 9,550 tons.
- 3) No evidence of direct mortality of Pacific herring by oil was observed.
- 4) Because there was no observations of direct mortality of Pacific herring or that spawning aggregations were fouled by the oil, the incremental growth hypothesis was not tested.
- 5) Because there was no observation of direct mortality or injury by the oil to stocks or habitats, no methods or strategies for restoration were investigated.
- 6) This project was terminated after one year and no further analyses have been completed.

APPENDIX B

Westward Region Procedures for Collecting Data from Test and Commercial Fishing Catches

INTRODUCTION

Herring from the commercial catch and test fishing are sampled for sex, size and age annually by field crews in coastal waters of the state from Ketchikan to Kotzebue to form a data base essential to the management of the state's herring resources. This information is drawn upon by management and research biologists for monitoring and regulating harvest levels, determining run timing, entry patterns and distribution of herring arriving on the spawning grounds, monitoring sexual maturity and age composition of herring spawning populations, developing methods to forecast herring abundance and determine optimum spawning goals, and to gain a better understanding of the biology of each stock. The usefulness of this AWL data depends on the manner and accuracy in which the samples were taken.

This manual was prepared as a guide for collecting information on age, sex, maturity, length, weight and fecundity of herring and recording the appropriate data on A-W-L mark-sense forms. Also included are methods used for collecting similar information for capelin and other fishes encountered during herring sampling. The sampling and recording procedures are listed in a logical order of activity and should be followed in sequence to develop accurate sampling techniques.

Responsibility for accuracy lies first with the primary data collector(s). Above all, KEEP THE MARK-SENSE FORMS FLAT, DRY AND CLEAN. Fish gurry and water curling will cause data to be incorrectly read. Project supervisors will return sloppy or incomplete data to individual collectors. Each form shall be marked with the data recorder's and interpreter's initials.

When using the reverse side of the mark-sense form to record data, the sheet code must be transferred on to the extreme left hand column of the back page. To transfer the code, fold the form over (without creasing) so that both code columns are visible and mark the corresponding number blocks onto the back grid.

Please read all the instructions carefully so that information is collected and recorded accurately and properly. Process all fishes within 48 hours of capture. Use a number 1 (or 2) lead pencil to record data and write labels. Please print legibly.

If you have comments or suggestions for improving sampling methods or this manual, please contact Larry Malloy or Len Schwarz.

EQUIPMENT LIST

1. Plain glass microscope slides (25 x 75 x 1mm)
2. Forceps
3. Scissors
4. Scalpel
5. Lead pencils (number 1 or 2)
6. Small beakers (at least two)

7. Wide mouth sample jars containing Gilsons Fluid (fecundity samples)
8. Ziplock plastic bags
9. Measuring board (calibrated in mm)
10. Dial-a-Gram or Lume-O-Gram scale
11. Small vials with caps (otolith sampling)
12. Labels
13. Paper towels
14. Mucilage glue
15. Water
16. Ethanol or glycerol (otolith sampling)
17. A-W-L MarkSense data forms
18. Formalin
19. Eyedropper (otolith sampling)
20. Stick-on white labels 5/8 inches by 7/8 inches.

METHODS

Herring

I. AWL Labeling

- A. Before any fish are handled, label the waterproof A-W-L mark-sense form(s) with a soft No. 1 or (2) pencil referring to (Figures 1a, 1b, and 1c).
 1. Leave the mark sense spaces blank if you are uncertain of a factor i.e. district number. These will be filled in in town.
 2. Enter the following information in the blank space between the LOCATION heading the and WEIGHT and AGE heading.
 - a. Sampler's name
 - b. Sample number: each sample should start with the crew leader's initials and then be numbered sequentially by sample.
 - c. Location: the exact location where the sample was CAUGHT is very important. Note the distance from the nearest headland (i.e. 2 miles N.E. Rocky Point). In the Port Moller and Canoe Bay fisheries refer to chart provided (Figure 2 and 2A) and record the nearest headland and subsection number.
 - d. Date: record the date the fish were CAUGHT on
 - e. Source: record how the fish were taken. i.e. commercial seine sample, variable mesh gillnet, seine test set, etc.
 - f. Vessel: record the name of the vessel the sample was taken from.
 - g. Collector: record the name of the person who collected the sample from the vessel or cannery.

3. Additional information should be entered on the back of the AWL form under comments. Such comments could include estimated size of the delivery, roe percentage, or other background information. If a sample contains more than 30 fish, it will require more than one AWL form. In the top right hand corner, write in which page of the sample it is (i.e. page 1 of 3; in other words this is the first page of a sample that contains 3 pages).

II. Filling out AWL Forms

- A. When entering data, blacken the entire block for its full length and width (█). Be sure to mark all the way from the top to the bottom.
 1. A single light pencil mark in the block is not acceptable (—)
 2. If a mistake is made, erase the mistake as completely as possible without rubbing away the paper and be sure to thoroughly blacken the correct mark to prevent a data entry error when the forms are machine processed.
- B. Refer to the area code for a listing of designated A-W-L mark-sense codes (Figures 1b and 1c).

III. Labeling slides

- A. Determine the number of microscope slides needed for mounting herring scales.
 1. Scales will be mounted on plain slides with labels on one end.
 2. Each slide will contain a maximum of 10 scales. One scale from each of 10 herring.
- B. Label each slide with 5 lines of information (Figure 1a).
 1. General Area: Write in either North or South Peninsula, Kodiak, Chignik, etc.
 2. Catch location. Enter the exact location the fish were taken in. Do not record where the tender is but where the fish were harvested.
 3. Catch date. Enter the date that the fish were harvested on.
 4. Sample number. Enter the sample number. This should correspond with the sample number of the AWL form you are using.
 5. Scale number. Scale numbers should start with 1 and continue in multiples of 10. (i.e. 1-10, 11-20, 21-30, 31-40, 41-50, 51-60). If a sample contains 90 samples there will be 3 AWL forms labeled page 1 of

3, page 2 of 3, and page 3 of 3. Page 1 will have length and weight data corresponding to scales 1-30, Page 2 31-60, and Page 3 61-90.

- C. Each sample and day should begin with a new AWL form.

IV. Measurements and Observations

- A. **IMPORTANT:** After each herring is measured, weighed, sexed, etc., it should be placed aside in the same order it was sampled so that the scale taken will correspond to the correct herring specimen number (Figure 1a).
- B. Standard length must be measured for every herring sampled unless the specimen has been too badly mangled (Figure 3).
1. Place each herring on the measuring board so that its anterior extremity is against the stop at the 0 mm line of the ruler (make sure the herring's mouth is closed).
 2. Locate the area where the anal (tail) fin rays meet the hypural plate by sharply bending the tail and noting the location of the crease.
 3. Record the measurement (to the nearest mm) from the anterior most extremity of the herring (the tip of the lower jaw) to the middle of the crease formed when the tail is bent.
 4. Length is recorded on the A-W-L form by marking the appropriate column blocks.
- C. Sex must be determined for every herring sampled, and appropriate column 1-4 marked under the SEX heading.
1. If herring are not ripe and running eggs or milt, they must be dissected to visually inspect the gonads.
 2. If herring are immature (virgin), it is not possible to determine the sex without use of a microscope. Simply record these specimens as juveniles on the A-W-L coded as 3.
 3. If specimens cannot be sexed for some other reason (i.e. specimen badly mutilated, etc.) record as unknown on the A-W-L form coded as 4.
- D. Sexual maturity index must be determined for every specimen whenever possible. Use the guide (Figure 1c to identify the appropriate Gonad Maturity number and mark the corresponding GONAD INDEX column block.

V. Scale Sampling

- A. Only one readable scale will be taken from each herring with a maximum of 10 scales placed on each slide (Figure 1a).
- B. Remove each scale from one of the preferred body areas (Figure 3) on the left side of the fish (right side used as alternate site if necessary) using forceps. Body area locations are numbered in order of preference (location 1 is most preferred; location 3 is least preferred). If stock separation is intended find a scale form the blackened area only (Figure 3) and mark P in the margin next to that fish. You will be instructed if this is necessary.
- C. Dip each scale in clean water, rub between thumb and forefinger to remove dirt and slime, examine (hold up to a light) for regeneration (regenerated scales appear blurred in the center), DISCARD IF REGENERATED REPEATING PROCEDURE UNTIL A SUITABLE SCALE IS LOCATED.
- D. To mount a scale on the glass slide, dip the scale into the mucilage glue solution, (1 part mucilage glue: 10 parts water), shake off excess solution, and place the scale onto the slide making sure the unsculptured (concave) side of the scale is facing down and the anterior margin (portion embedded in the integument of the fish) is facing towards the bottom of the slide. The ridges on the sculptured side of the scale can be felt with a fingernail or forceps. Make certain that scales are placed on the slides in the positions corresponding to the correct specimen number on the A-W-L form (Figure 1a).
- E. Press each scale firmly against the slide with a paper towel after mounting to remove excess glue from underneath the scale. Press firmly and blot excess glue with the towel. (Too much pressure, however, can break your slide.)
- F. Store completed scale mounts in slide boxes to avoid loss or breakage.
- G. Mark the age of each specimen in the appropriate blocks on the A-W-L forms after the scales have been aged. A regenerated scale is marked as 18, illegible as 19 and missing as 20 in the age column.
- H. Completed A-W-L mark-sense forms should be stored in an appropriate notebook, file, etc.

VI. Otolith Sampling (see following Capelin sections I and III).

- A. Do Not Collect otoliths unless directed to in the project operational plan.

CAPELIN

- I. Preparations Prior to Data Collection (Do Not Collect otoliths unless directed to in your project operational plan).
 - A. Mix a solution of 1 part water to 1 part ethanol or use 100% glycerol.
 - B. Determine the number of vials needed for collecting otoliths.
 1. Each vial will hold one pair of otoliths.
 2. Thirty vials are required for every complete A-W-L form.
 - C. Place a label in each vial with the following information.
 1. Sample number. This should correspond with the sample number on the AWL form being used.
 2. Otolith Number. This should correspond with the A-W-L number which contains the appropriate length and sex for that otolith (i.e. 1-30 on the first page of the sample, 31-60 on the second page of the sample, etc.)
 3. Species. Either capelin or herring.
 4. Date. Put the date the fish were captured on.
 5. Location. Put the area of capture.
 6. Sampler's name.
 - D. Make certain that capelin samples from test fishing catches have been correctly subsampled and contain equal numbers of males and females (see Test Fishing-Variable Mesh Gillnets, Operational Plan).
- II. Measurements and Observations
 - A. IMPORTANT: After each capelin is measured, weighed, sexed, etc. it should be placed side in the same order it was sampled so that the otoliths taken will correspond to the correct capelin specimen number (Figure 4). All capelin data will be recorded on A-W-L mark-sense forms similar to herring data.
 - B. Fork length must be measured for every capelin in a sample, unless the specimen has been too badly mangled (Figure 5).
 1. Place each capelin on the measuring board so that its anterior extremity is against the stop at the 0 mm line of the ruler (make sure the capelin's mouth is closed).
 - C. Weight to the nearest g must be taken for every capelin in the sample, unless a portion of the body is missing.

- D. Sex must be determined from every capelin in the sample, whenever possible.
1. Sexually mature males can be distinguished by the prominent raised "hairy" bands of scales along their sides (above the lateral line).
 2. If capelin are not ripe and running eggs and sperm (and if males cannot be sexed externally), they must be dissected so that gonads can be visually inspected.
 3. If specimens cannot be sexed, indicate this on the A-W-L form. Do not record these specimens as juveniles unless you have good reason to believe they are immature.
- E. Sexual maturity index must be determined for every specimen whenever possible. use the appropriate code (Figure 1C). Although the code guide was developed specifically for herring, it is general enough to use for most fishes, if specific gonad measurements are ignored.

III. Otolith Sampling

- A. One pair of otoliths will be taken from each capelin and placed in an individual vial.
- B. To find the otoliths make a shallow, horizontal cut beginning just behind the head and extending to the snout. This will expose the brain cavity (Figure 4).
- C. The otoliths will be found on either side of the skull behind the eyes. (There are three pairs of otoliths located within the chambers of the inner ears. The largest pair, sagitta, are the easiest to find and remove.)
- D. Remove the otoliths with forceps and clean each specimen between your fingers.
- E. Place the pair in an appropriately labeled vial, fill with the ethanol solution or glycerol and cap tightly.
- F. If an otolith breaks during the extraction process, place all pieces in the via.

Other Fishes

Other fishes, such as yellowfin sole, may also need to be sampled in some areas. Process these specimens using the methods outlined for capelin (see above). However, use fork length on species with forked tails and total length on species that do not have forked tails. Indicate on A-W-L form under "remarks" when total length is used.

DESCRIPTION - Accurately state where sample was taken.

YEAR-MONTH-DAY - Date on which samples were collected. Remember - only one date per NWL.

LENGTH MEASUREMENT - SL = standard; FL = fork.

AGE MEASUREMENT - SC = scale; OT = otolith.

FISHERY - BC = bait catch; TI = trawl incidental; TE = test; CO = commercial; SU = subsistence.

GEAR - Type of gear used to collect samples. Obtain from the code guide (Figure 2A-B).

MESH SIZE - If gill net used to collect samples indicate actual mesh size in inches.
 00 = dropout (fish sampled from unknown mesh size).

NET LENGTH - Record length of net in fathoms.

SET/SAMPLE # - Number assigned tent fish sets only. Number sequentially starting with 1.
 Use a separate numbering sequence for each district and section.

TIME SET - Actual time test net set. Use 24 hour (military) time format. For test fishing only.

HOURS FISHED - Total hours (in tenths) test net fished.

PAGE - Number sequentially starting with 1. Use a separate numbering sequence for each district, section and gear type. Be sure this number corresponds to the correct scale slide number.

LENGTH - Record all lengths in millimeters.

WEIGHT - Record all weights in grams.

OBTAIIN THE FOLLOWING INFORMATION FROM THE CODE GUIDE (Figure 2A-B).

AWL CODES

| Gear | Sex | Specimen Age | Mesh Size |
|--|---|---|----------------------------------|
| 1 = Variable mesh gillnet - floating 2 = Variable mesh gillnet - sinking 3 = Set gillnet 4 = Drift gillnet 5 = Purse seine 6 = Beach Seine 7 = Otter trawl 8 = Hand picked 9 = Dip net | 1 = Male 2 = Female 3 = Juvenile 4 = Unknown | 1-17 = actual fish age in years 18 = regenerated 19 = illegible 20 = missing | 1-4 7/8 = inches 00 = dropout |

| Maturity | GONADS (Relative Maturity) Key Characteristics |
|----------|---|
| 1 | Virgin herring. Gonads very small, threadlike, 2-3 mm broad. Ovaries wine red. Testes whitish or grey brown. |
| 2 | Virgin herring with small sexual organs. The height of ovaries and testes about 3-8 mm. Eggs not visible to naked eye but can be seen with magnifying glass. Ovaries a bright red color; testes a reddish grey color. |
| 3 | Gonads occupying about half of the ventral cavity. Breadth of sexual organs between 1 and 2 cm. Eggs small but can be distinguished with the naked eye. Ovaries orange; testes reddish grey or greyish. |
| 4 | Gonads almost as long as body cavity. Eggs larger varying in size, opaque. Ovaries orange or pale yellow; testes whitish. |
| 5 | Gonads fill body cavity. Eggs, large round; some transparent. Ovaries yellowish, testes milkwhite. Eggs and sperm do not flow, but sperm can be extruded by pressure. |
| 6 | Ripe gonads; eggs transparent; testes white; eggs and sperm flow freely. |
| 7 | Spent herring. Gonads baggy and bloodshot. Ovaries empty or containing only a few residual eggs. Testes may contain remains of sperm. |
| 8 | Recovering spents. Ovaries and testes firm and larger than virgin herring in Stage II. Eggs not visible to naked eye. Walls of gonads striated; blood vessels prominent. Gonads wine red color; (this stage passes into Stage III). |

1st Ed., Feb. 1926 C 1943-604

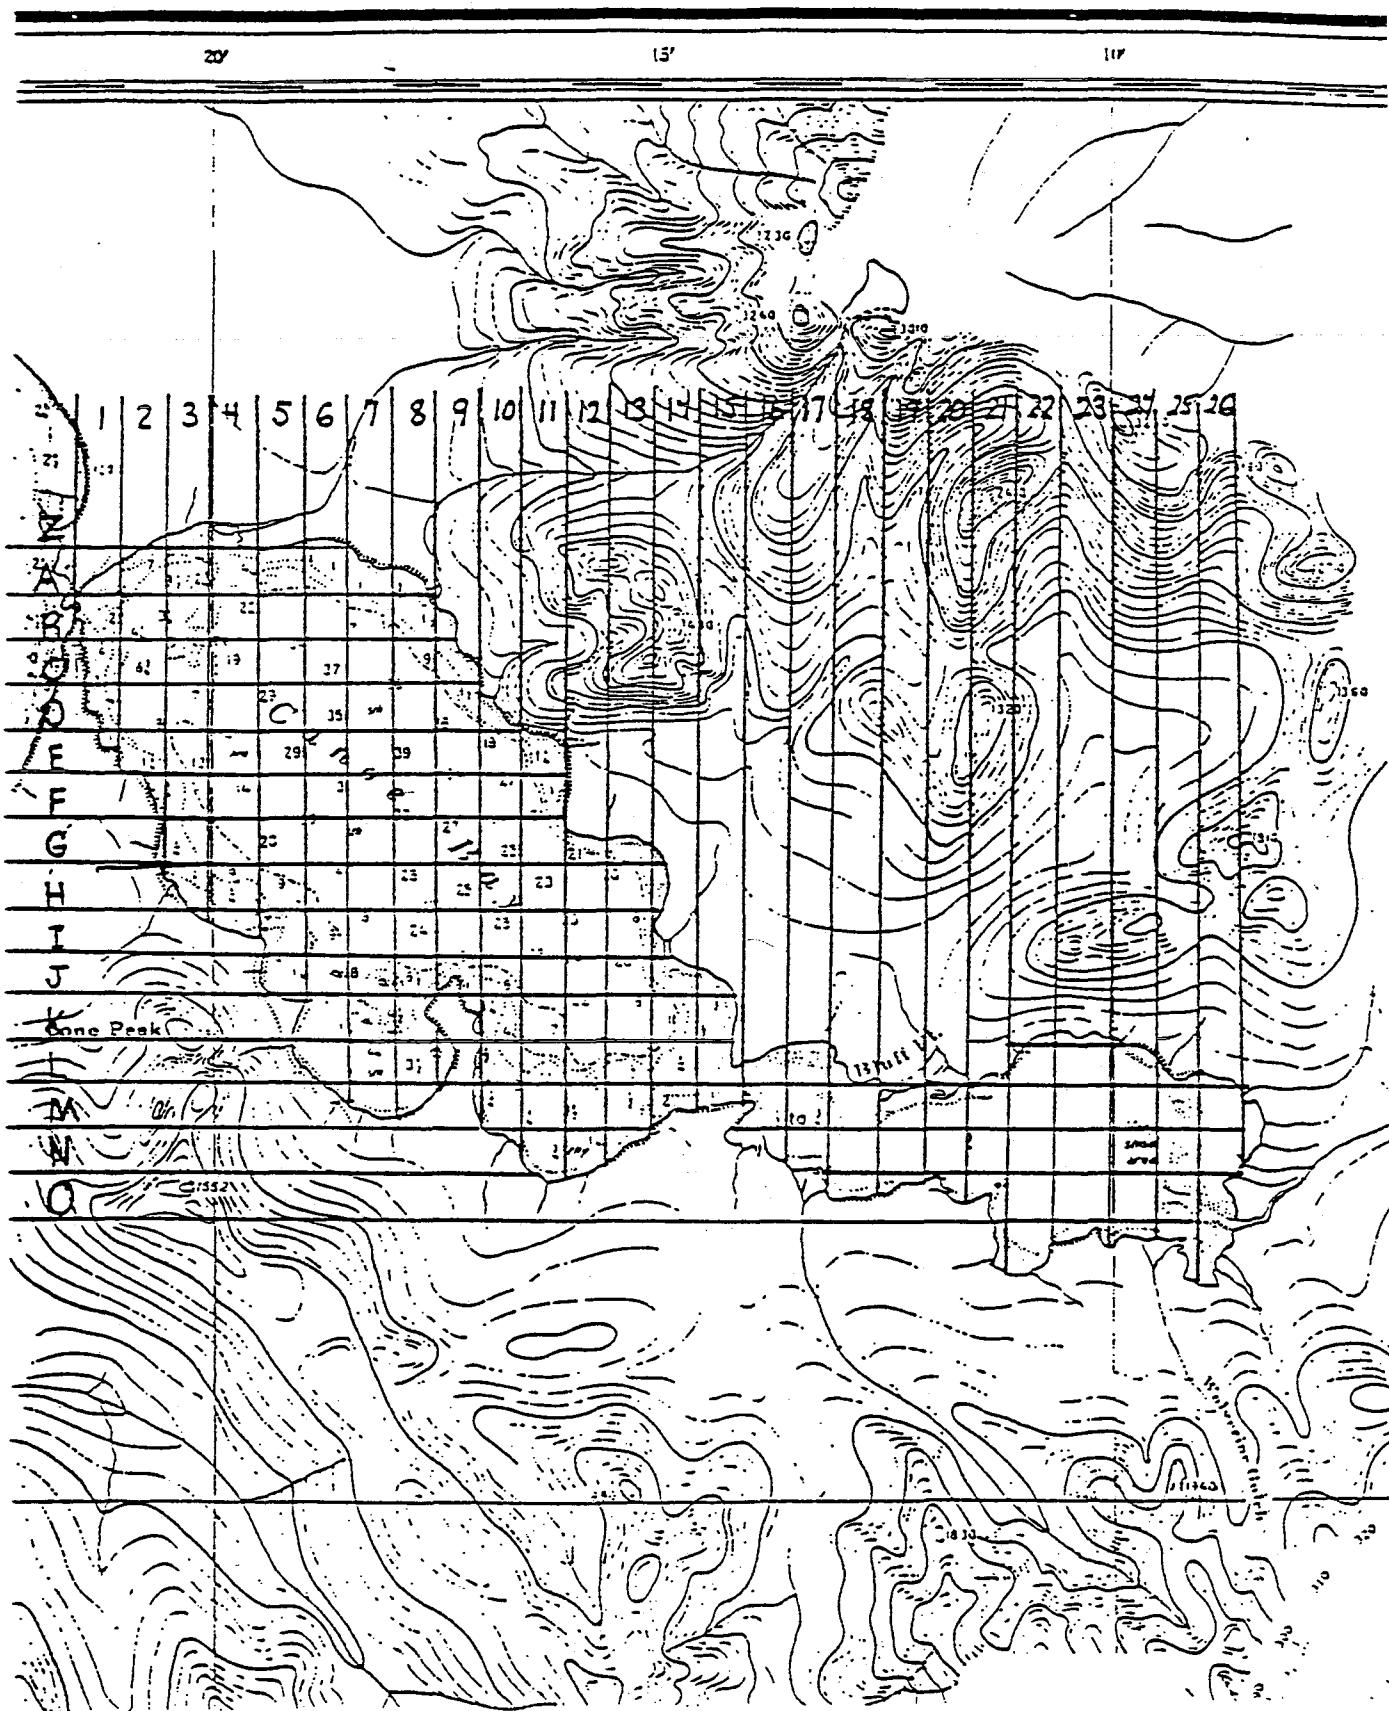

Figure 2 B.

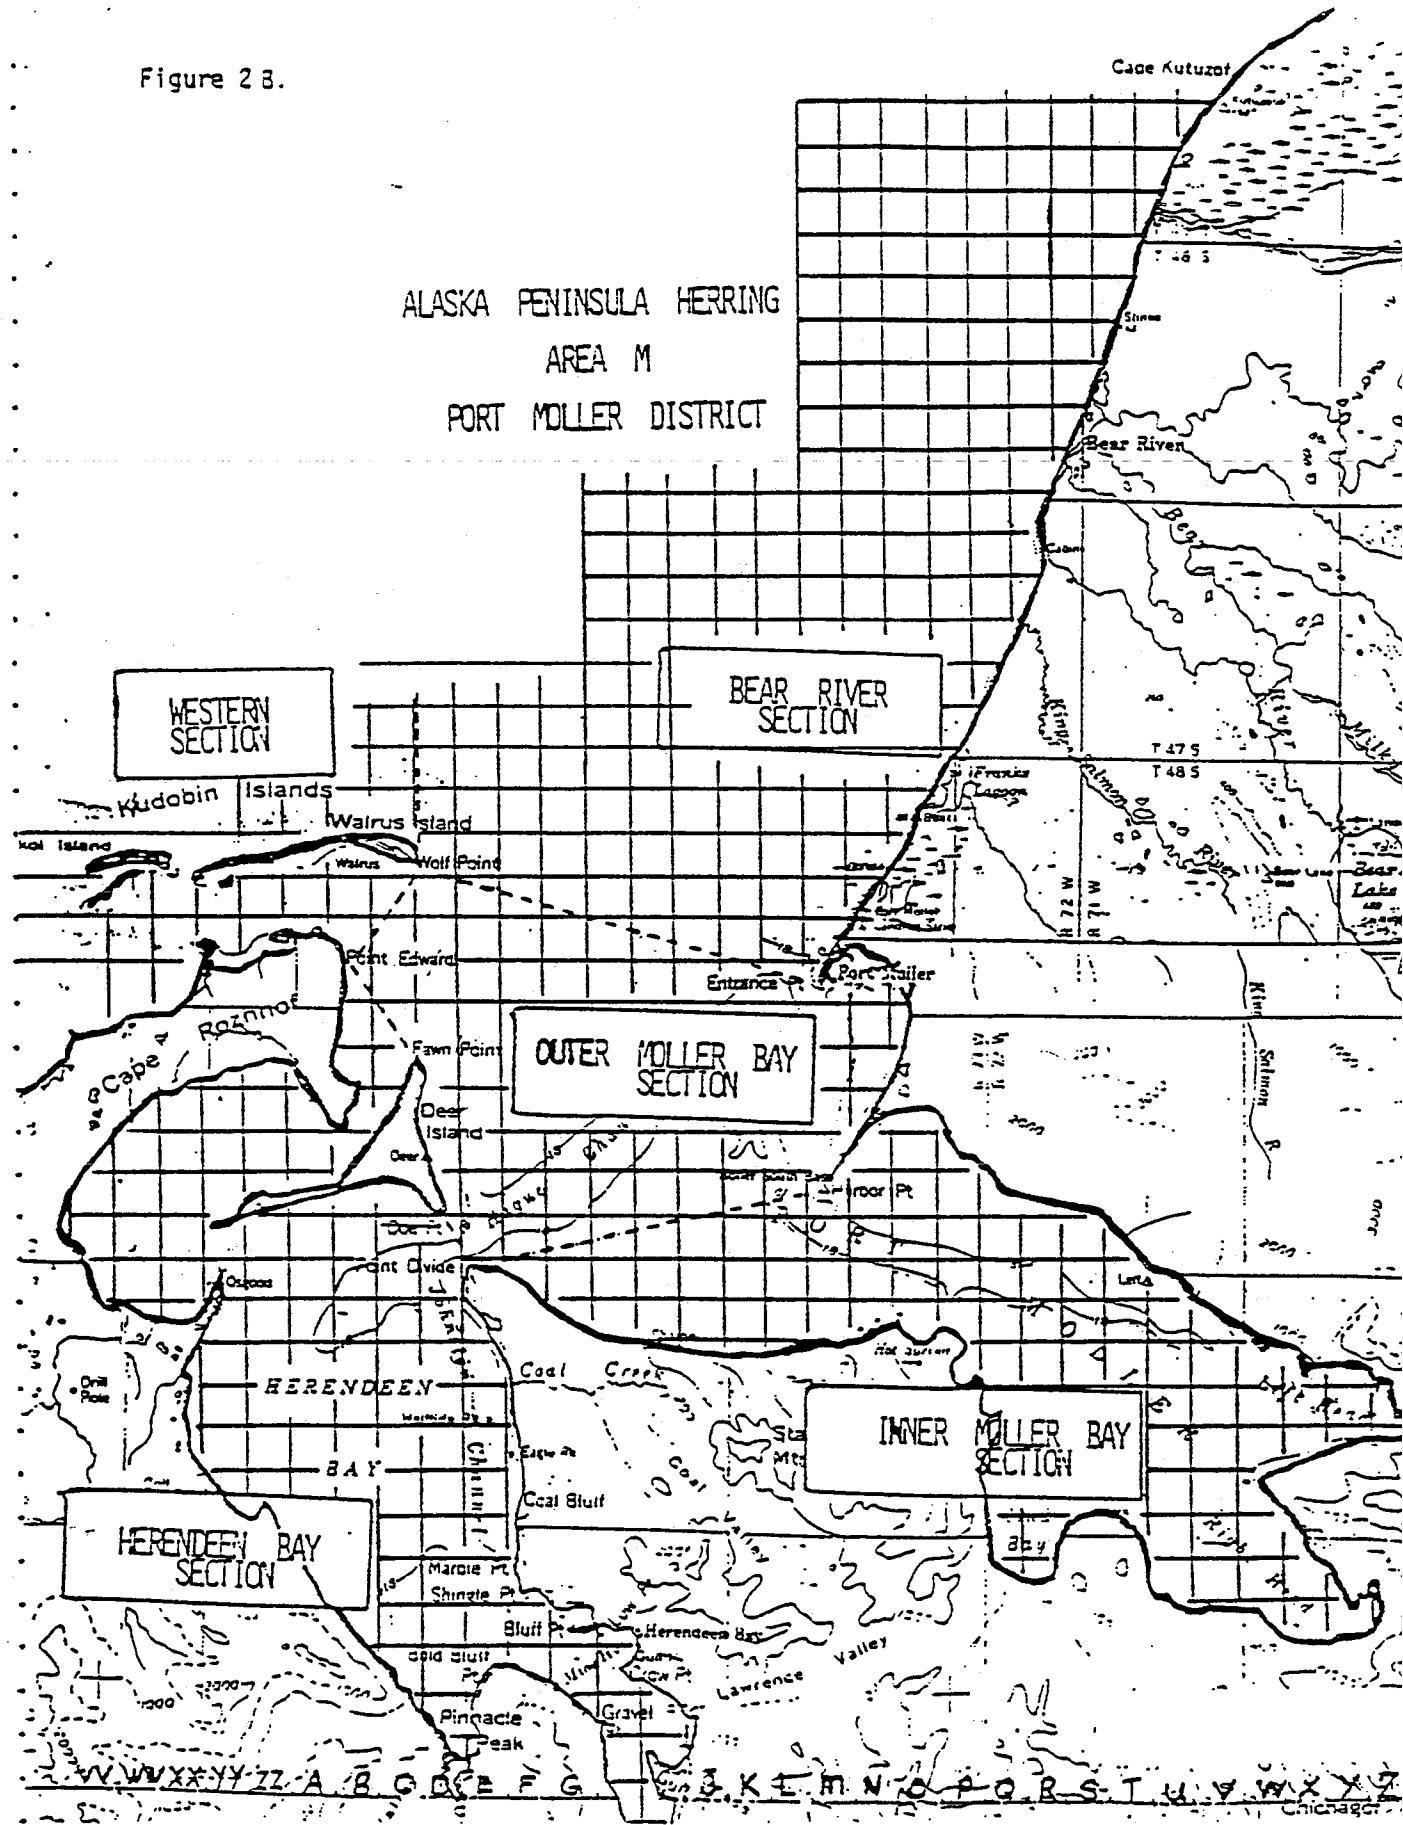

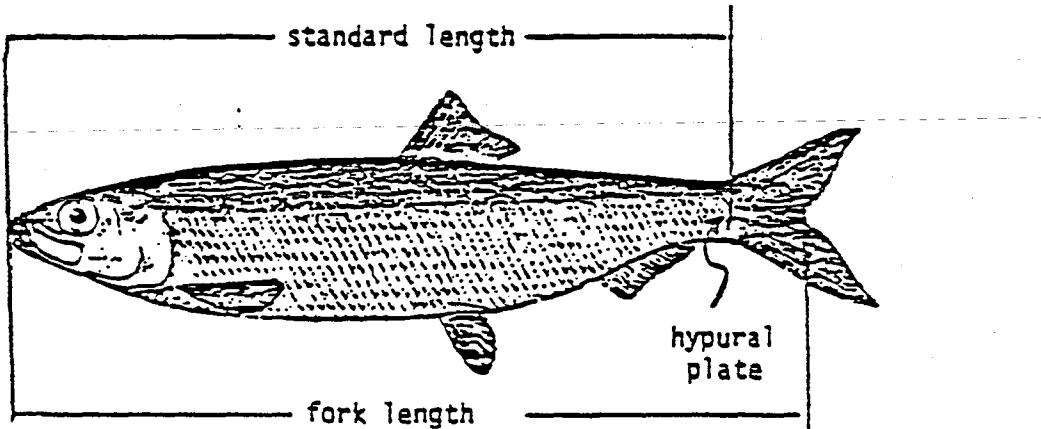

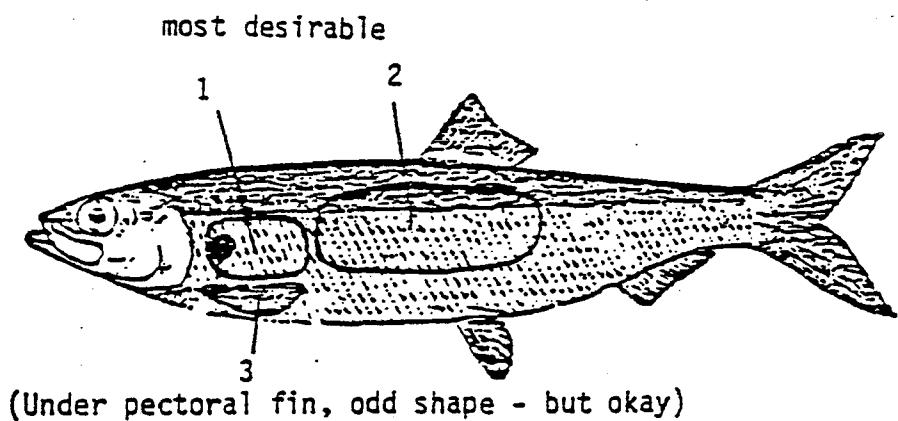

Figure 3.

Standard Length: the straight line distance from the anterior most part of the fish, including the lower jaw with the mouth closed, to the end of the vertebra (hypural plate). The vertebra end is recognized by the folding of the skin on an unskinned fish when the tail is sharply bent.
(Use)

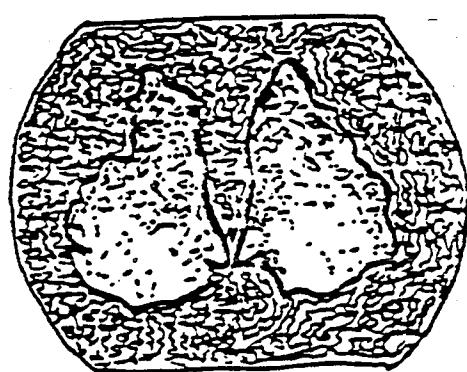

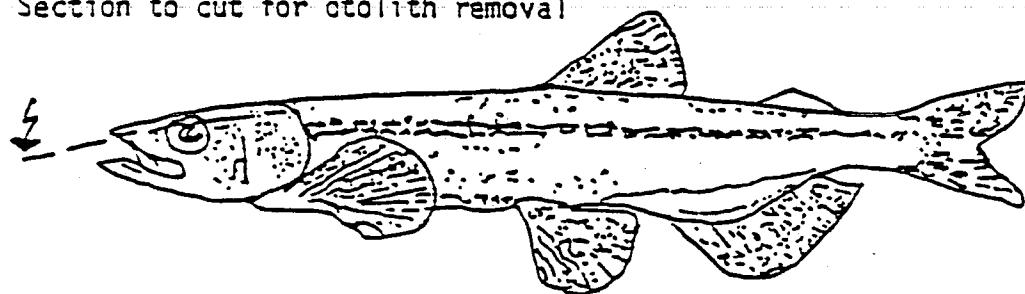

Fork Length: the straight line distance from the anterior most portion of the snout or upper jaw to the extreme end of the center of the caudal fin. It does not include a projecting lower jaw.
(Don't Use)

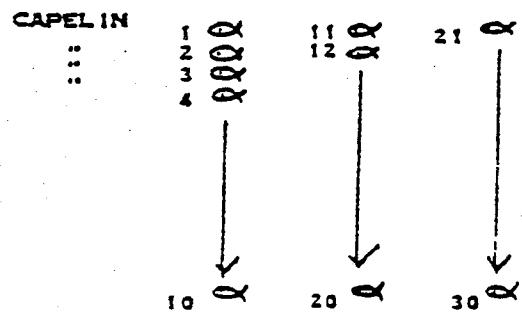

Preferred body areas from which to collect scales for aging are shown above. Scales should be collected from the left side of the herring if possible. If no scales are present in any of the above areas on the left side, check the right side (using the same preference sequence). If scales are really scarce, take any good one you can find that is not regenerated.

Figure 4.

Section to cut for otolith removal

Capelin Otoliths

CAPELIN SHOULD BE POSITIONED
SO AS TO MATCH ENTRIES ON
AWL FORMS. THIS IS IMPORTANT
FOR LATER SCALE SAMPLING.
